# **RESPIRATION**

• All living things respire. Respiration is a process that includes breathing. The movement of air in and out of the body and vice-versa is known as breathing.

For example, animals such as earthworms breathe through their skin; fishes use gills for breathing and plants exchange gases through tiny pores called stomata, which are present mainly on the surface of leaves.

Changing your Tomorrow

# **RESPIRATION AND BREATHING**

 Respiration is the oxidation of nutrients in the living cells to release energy for biological work. Breathing is the exchange of O<sub>2</sub> from the atmosphere with CO<sub>2</sub> produced by the cells.

![](_page_2_Picture_2.jpeg)

#### **AEROBIC RESPIRATION AND ANAEROBIC RESPIRATION**

| Aerobic respiration  | Anaerobic respiration                        |
|--|--|
| It occurs in the presence of $O_{2}$ .   | It occurs in the absence of O <sub>2</sub> . |
| It involves the exchange of gases<br>between an organism and outside<br>environment. | Exchange of gases is absent.                 |
| It occurs in the cytoplasm and mitochondria.   | It occurs only in the cytoplasm.             |
| It always releases CO <sub>2</sub> and H <sub>2</sub> O.                             | End products may vary.                       |
| It yields 36 ATP.  | It yields 2 ATP.                             |
| Example: Cells in our body   | Example: Yeast and muscle cells              |

Adenosine triphosphate (ATP) is the universal unit of energy used in all living cells. It is the very basic molecule which meets our energy needs and is formed in the later steps of glucose oxidation.

General body surface E.g. lower invertebrates (sponges, coelenterates, flatworms etc).

![](_page_4_Picture_1.jpeg)

#### **Gills (Branchial** respiration) E.g. fishes, tadpoles, prawn.

![](_page_4_Picture_3.jpeg)

![](_page_4_Picture_4.jpeg)

#### **RESPIRATORY ORGANS**

![](_page_4_Picture_6.jpeg)

![](_page_4_Picture_7.jpeg)

![](_page_4_Picture_8.jpeg)

Lungs (Pulmonary respiration) E.g. most vertebrates.

![](_page_4_Picture_10.jpeg)

![](_page_4_Picture_11.jpeg)

**Tracheal tubes** E.g. Insects, centipede, millipede, spider.

### **MECHANISM OF BREATHING**

![](_page_6_Figure_1.jpeg)

## NOSE, PHARYNX, LARYNX AND TRACHEA

![](_page_7_Figure_1.jpeg)

![](_page_7_Picture_2.jpeg)

## NOSE, PHARYNX, LARYNX AND TRACHEA

Air is breathed through:

Nostrils — pharynx — larynx — trachea —bronchi — bronchioles — alveoli.

This forms the entire respiratory tract.

\* Air can either from nose or mouth and then travel through the throat( pharynx), larynx and finally enters the windpipe known as trachea.

\* The trachea further gets divided into two branches( hollow tubes) known as bronchi- the left and right bronchus that leads to the left and right lung respectively.

![](_page_8_Figure_6.jpeg)

![](_page_8_Picture_7.jpeg)

# LARYNX

- The larynx has a kind of lid to prevent food from entering the windpipe and lower airways: This lid is called the epiglottis. It is attached to the top part of the larynx, where it can close the entrance to the larynx.
- When we swallow, it moves down to keep any food or liquids out of the windpipe. By using ligaments and muscles, the vocal cords can be opened and closed, tensed and held together closely which looks like the curtains being closed.
- When we breathe out, air flows through the gap between the vocal cords. Depending on their exact position, this causes them to vibrate in different ways, resulting in different tones.
- Together with the movements of the <u>tongue</u> and mouth, very different sounds can be produced at different volumes, allowing us to speak and sing.

![](_page_9_Figure_5.jpeg)

# BRONCHI

![](_page_10_Figure_1.jpeg)

The <u>trachea</u> divides into the right and left primary <u>bronchi</u>. The bronchi branch into smaller and smaller passageways until they terminate in tiny air sacs called <u>alveoli</u>. The <u>cartilage</u> and <u>mucous membrane</u> of the primary bronchi are similar to that in the trachea. As the branching continues through the <u>bronchial tree</u>, the amount of <u>hyaline</u> <u>cartilage</u> in the walls decreases until it is absent in the smallest <u>bronchiole</u>.

![](_page_10_Picture_3.jpeg)

# LUNGS

![](_page_11_Figure_1.jpeg)

The two lungs, which contain all the components of the bronchial tree beyond the primary bronchi, occupy most of the space in the <u>thoracic cavity</u>. The lungs are soft and spongy because they are mostly air spaces surrounded by the alveolar cells and elastic <u>connective tissue</u>.

![](_page_11_Picture_3.jpeg)

#### **ALVEOLUS**

The <u>alveolar ducts</u> and alveoli consist primarily of simple squamous epithelium, which permits rapid <u>diffusion</u> of <u>oxygen</u> and <u>carbon dioxide</u>. Exchange of gases between the air in the lungs and the <u>blood</u> in the <u>capillaries</u> occurs across the walls of the alveolar ducts and alveoli.

![](_page_12_Figure_2.jpeg)

Changing your Tomorrow

# **GASEOUS EXCHANGE IN LUNGS**

Oxygen gets carried by the haemoglobin of the red <u>blood cells</u> since it has a great affinity for oxygen. Each haemoglobin molecule binds to four molecules of oxygen. This oxygen that is picked up by haemoglobin gets transported by the blood to various tissues. As carbon dioxide is more soluble in water than oxygen, they are transported in the dissolved form in our blood, while some are also transported by haemoglobin. Not all of the carbon dioxide formed is expelled from the body as some of it react with water to form compounds useful for life processes.
