

# ASSIGNMENT

Q 1) Write 4 points of difference between aerobic and anaerobic respiration.

Ans)

Aerobic Respiration

Anaerobic Respiration

- (i) Aerobic respiration refers to complete breakdown of metabolic fuels in presence of oxygen.
- (i) Anaerobic respiration refers to partial breakdown of metabolic ~~fuel~~ fuel (glucose) in absence of oxygen.
- (ii) It includes glycolysis, citric acid cycle and oxidative phosphorylation. The first two processes take place in the cytoplasm while the last one occurs in mitochondria.
- (ii) Glycolysis is followed by ethanol fermentation (occurs in yeast) or lactic acid fermentation (in muscle and microbes like Lactic acid bacteria).

- (iii) The end products are carbon dioxide and water
- (iv) Owing to complete oxidation of glucose a large amount energy is produced (36- 38) ATP Molecules are produced.
- (iii) End products are ethanol +  $\text{CO}_2$  for ethanol fermentation and lactic acid for lactic acid fermentation.
- (iv) Incomplete oxidation of glucose does not release all stored energy and only 2 ATP molecules.

Q.2) What are the different ways in which glucose is oxidised to provide energy in various organisms?

Ans) Breaking down of glucose involves two processes. In the first step, it is broken into three-carbon molecules called pyruvate. The pyruvate is further broken down into energy in the following different ways:

- (a) Aerobic Respiration: In this case, pyruvate is broken down into water and carbon dioxide along with the release of energy. It commonly occurs in the mitochondria of cells.
- (b) Anaerobic Respiration: In anaerobic respiration breakdown of pyruvate takes place in presence of oxygen to give rise 3 molecules of carbon dioxide and water. And ~~pyruvate~~ pyruvate is converted into ethanol and carbon dioxide.

Q-3-> The autotrophic mode of nutrition requires:

- (d) All of the above
- { (a) Carbon dioxide and water  
(b) Sunlight  
(c) Chlorophyll }
