2th July

1) If a particle of charge  $q$  is moving with velocity  $v$  along the  $z$ -axis and the magnetic field  $B$  is acting along the  $x$ -axis, use the expression  $\vec{F} = q(\vec{v} \times \vec{B})$  to find the direction of the force  $F$  acting on it. A beam of proton passes undeflected with a horizontal velocity  $v$ , through a region of electric and magnetic fields, mutually perpendicular to each other and normal to the direction of the beam. If the magnitudes of the electric and magnetic fields are  $100 \text{ kV/m}$  and  $50 \text{ mT}$  respectively, calculate

(a) velocity  $v$  of the beam.

(b) the force with which it strikes a target in a screen if the proton beam current is equal to  $0.80 \text{ mA}$ .

$$\Rightarrow \vec{F} = q\vec{v} \times \vec{B}$$

$$\text{Given } \vec{v} = v\hat{k}, \vec{B} = B\hat{i}$$

$$\vec{F} = q(v\hat{k}) \times (B\hat{i}) = qvB\hat{j}$$

That ~~is~~ is force acting along  $y$ -axis.

(a) For a beam of charged particle to pass undeflected cross electric and magnetic field, the condition is that electric and magnetic forces, on the beam must be equal and opposite.

$$eE = eVB$$

$$V = \frac{E}{B}$$

$$\text{Given } E = 100 \text{ kV/m} = 100 \times 10^3$$

$$B = 50 \times 10^{-3} \text{ T.}$$

$$V = \frac{100 \times 10^3}{50 \times 10^{-3}}$$

$$= \underline{\underline{2 \times 10^6 \text{ m/s}}}$$

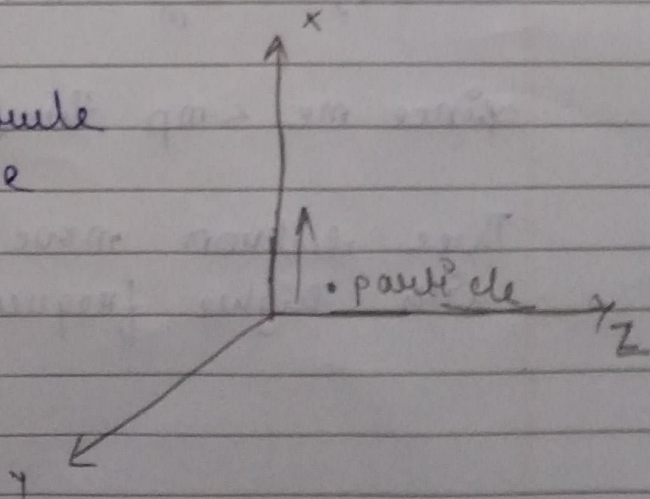

- b) The beam strikes the target with a constant velocity so force exerted on the target is zero. However if proton beam comes to rest, it exerts a force on the target equal to rate of change of linear momentum of the beam.

$$F = \frac{\Delta p}{\Delta t} = \frac{mv}{\Delta t} = \frac{mv}{q/i} = \frac{mvi}{q} = \frac{mvi}{ne}$$

where  $n$  is the number of protons striking the target per second.

- 2) A beam of  $\alpha$  particles projected along  $+x$ -axis, experiences a force due to a magnetic field along the  $+y$ -axis. What is the direction of the magnetic field?

- $\Rightarrow$  By Fleming's left hand rule magnetic field must be along negative  $z$ -axis.

3) Define one tesla using the expression the magnetic force acting on a particle charge  $q$  moving with velocity  $v$  in a magnetic field  $B$ .

⇒ when a charge of  $1\text{C}$ , moving with velocity  $1\text{m/s}$ , normal to the magnetic field, experiences a force  $1\text{N}$ , the magnetic field is said to be one tesla.

4) A proton and an electron travelling along parallel paths enter a region of uniform magnetic field, acting perpendicular to their paths. Which of them will move in a circular path with higher frequency?

⇒ Electron move in a circular path with a higher frequency.

$$\frac{mv^2}{r} = qvB, \quad r = \frac{mv}{qB}$$

$$\omega = \frac{v}{r} = \frac{qB}{m}$$

$$\omega = 2\pi f \Rightarrow \frac{qB}{m} = 2\pi f \Rightarrow f \propto \frac{1}{m}$$

since  $m_e < m_p$  therefore  $f_e > f_p$ .

Thus electron move in circular paths with higher frequency.

5) Two photons of equal kinetic energies enter a region of uniform magnetic field. The first photon enters normal to the field direction while the second enters at  $30^\circ$  to the field direction. Name the trajectories followed by them.

$\Rightarrow$  When an electron enters normal to the field direction the trajectory is circular.

When an electron enters  $30^\circ$  to the field direction the trajectory is helical.
